1 Universal property

Universal property is a core concept in modern mathematics, it means the same properties but appears in different objects, in the language of category theory, it means the same diagram commutative in different categories. this section is to introduce some common universal properties from set theory to group theory and topology, it can be seen as a review of basic mathematics, and a good invitation for category theory.

1.1 Quotient

quotient is a method to see two different things as the same things via an equivalence relation: Let X be a non-empty set and \sim be an relation on X , if it satisfies

- reflexive: $x \sim x$
- symmetric: $x \sim y \Rightarrow y \sim x$
- transitive: $x \sim y, y \sim z \Rightarrow x \sim z$

Then we define \sim is an **equivalence relation** on X . So we can define the equivalence class of some element a of the set as

$$[a] = \{x \in X | x \sim a\}$$

then the **quoitent set** of X with respect to \sim is defined as

$$X / \sim := \{[a] | a \in X\}$$

but it is not the unique method to define quotient, the follwing statement gives different view.

Lemma 1.1. *Let X be a non-empty set, then the following statements are equivalent:*

- (1) *There is an equivalence relation \sim on X .*
- (2) *There is a surjective map $f : X \rightarrow Y$ to some set Y .*
- (3) *There is a partition of X , i.e. a family $P = \{A_i | i \in I, A_i \subset X\}$ such that the set can be written as the disjoint union of the family*

$$X = \bigsqcup_{i \in I} A_i$$

Proof. (1) \Rightarrow (2): Let $Y = X / \sim$ and define $\pi : X \rightarrow Y, x \mapsto [x]$, then it is easy to see that π is a surjective map.

(1) \Rightarrow (3): it is equivalent to prove that the equivalence class $[x]$ and $[y]$ is disjoint if $x \not\sim y$, otherwise they are equal.

(2) \Rightarrow (1): Define a relation on X by

$$x \sim_f y \iff f(x) = f(y)$$

It is a equivalence relation, and the equivalence class can be denoted by pre-image

$$[x] = f^{-1}(y)$$

where $y = f(x)$.

(3) \Rightarrow (1): Define a relation on X by

$$x \sim_P y \iff x \in A_i \wedge y \in A_i$$

for some $i \in I$, similarly the class can be denoted by

$$[x] = A_i$$

where $x \in A_i$ and $X / \sim_P = P$ actually. □

The application in the proof

$$\pi : X \rightarrow X / \sim, \quad x \mapsto [x]$$

is called the **quotient map**, it is a type of **natural map**, that means the definition of the map is unique and very natural. The statement (2) can be generalized to any map, not only surjective map, but the reason here I only state the surjective map is that (a) any map can be restricted to a surjective map; (b) the quotient map is surjective.

The universal property of quotient can be explained as following: we expect two objects are the same up to isomorphism, in the sense of set theory, that means there is a bijection between two sets, but it is not easy to construct a bijection directly, or sometimes we do not need know what the bijection exactly is. Now we take a map $f : X \rightarrow Y$, then we can **uniquely determine** a bijection between X / \sim_f and a subset of Y , and the bijection is induced by f and the quotient map, the correspondence can be

draw as following commutative diagram:

$$\begin{array}{ccc} X & \xrightarrow{f} & Y \\ \pi \downarrow & \searrow \exists! \bar{f} & \\ X/\sim_f & & \end{array}$$

We conclude the result of set theory as following:

Theorem 1.2 (UPQ-SET).

Let X, Y be two empty sets and $f : X \rightarrow Y$ a surjective map between them, then there is a unique bijection map $\bar{f} : X/\sim_f \hookrightarrow Y$ such that $f = \bar{f} \circ \pi$, where $\pi : X \rightarrow X/\sim_f$ is the quotient map.

Proof. The definition of \bar{f} is natural and uniquely by $f = \bar{f} \circ \pi$, for any $[x] \in X/\sim_f$, define

$$\bar{f}([x]) = f(x)$$

the map is well-defined, because if $[x] = [y]$, then $f(x) = f(y)$ by the definition of \sim_f . The relation \sim_f implies injection \bar{f} , surjection f implies surjection \bar{f} , so we finish the proof. \square

It is the simplest universal property of quotient, it can be generalized to other mathematics objects, but a little different, the map between two objects should preserve the structure, so the map will be some type of morphism, hence the quotient map should also be a morphism and the equivalence relation should be compatible with the structure. Let us consider the case of topological space.

In geometry view, a circle can be obtained by glueing the two endpoints of a line segment, for example we identify two endpoints of the interval $[0, 1]$ by the relation $0 \sim 1$, then we can get a quotient set $[0, 1]/\sim$, but how to define the topology on the quotient set such that it is a space homomorphic to circle \mathbb{S}^1 ? The answer is that the quotient map should preserve the topological structure, i.e. quotient topology is the smallest topology such that the quotient map is continuous.

Definition 1.1. Let (X, \mathcal{T}) be a topological space and \sim be an equivalence relation on X , the **quotient topology** on X/\sim is defined as

$$\mathcal{T}_\sim := \{U \subset X/\sim \mid \pi^{-1}(U) \in \mathcal{T}\}$$

where $\pi : X \rightarrow X/\sim, x \mapsto [x]$ is the quotient map.

We can complete the example just now, firstly we find a surjective map

$$f : [0, 1] \rightarrow \mathbb{S}^1, \quad f(x) = e^{2\pi i x}$$

It is easy to see that $0 \sim_f 1$ since $f(0) = f(1)$, and the relation is exactly the relation we want, so we can conclude a bijection $\bar{f} : [0, 1] / \sim_f \rightarrow \mathbb{S}^1$ such that $f = \bar{f} \circ \pi$ by UPQ-SET, by the condition that f and π are continuous, we can verify that \bar{f} is also continuous. To see whether it is a homeomorphism or not, we notice that \mathbb{S}^1 is a compact space, so we just need to verify that $[0, 1] / \sim_f$ is also a compact space (**a continuous bijection from a compact space to a Hausdorff space is automatically a homeomorphism**), that needs a properties of quotient space:

Claim 1.3. *Let X be a compact space and the graph of \sim be closed in X^2 , then quotient space X / \sim is also a compact space.*

Proof.

$$G = \{(a, b) \in X^2 | a \sim b\}$$

is the graph of \sim ,...

□

So we can prove that $[0, 1] / \sim_f$ is homeomorphic to \mathbb{S}^1 as above, and we can generalized the result to any similar case as following:

Theorem 1.4 (UPQ-TOPO).

Let (X, \mathcal{T}) be a topological space and (Y, \mathcal{J}) be a topological space, $f : X \rightarrow Y$ be a surjective continuous map, then there is a unique continuous bijection $\bar{f} : (X / \sim_f, \mathcal{T}_{\sim_f}) \rightarrow (Y, \mathcal{J})$ such that $f = \bar{f} \circ \pi$, where $\pi : X \rightarrow X / \sim_f$ is the quotient map.

Proof. By UPQ-SET, there is a unique bijection \bar{f} such that $f = \bar{f} \circ \pi$, now we will prove that \bar{f} is a homeomorphism. Take any open set U of Y , then

$$f^{-1}(U) = (\bar{f} \circ \pi)^{-1}(U) = \pi^{-1}(\bar{f}^{-1}(U))$$

since f is continuous, then $\pi^{-1}(\bar{f}^{-1}(U))$ is open in X , by the definition of quotient topology, $\bar{f}^{-1}(U)$ is open in X / \sim_f , so \bar{f} is continuous. □

Remark 1.1. Here we can not get that \bar{f} is a homeomorphism directly, because the quotient map is not only a continuous map, it is strong continuous: a map $f : X \rightarrow Y$ is called **strong continuous** if it satisfies

$$U \in \mathcal{T}_Y \iff f^{-1}(U) \in \mathcal{T}_X$$

An example of a continuous map but not strongly continuous is the map $f : \mathbb{R} \rightarrow \mathbb{R}, x \mapsto 0$, here we take $U = [-1, 1]$, then $f^{-1}(U) = \mathbb{R}$ is open, but U is not open.

So in the statement of UPQ-TOPO, if we add that f is strongly continuous (for example, f is an open map), then \bar{f} is furthermore a homeomorphism.

Finally, we study another basic object: group. Let G be a group and H be a subgroup of G , then the subgroup can induce an equivalence relation (verify) on G by

$$a \sim_H b \iff a^{-1}b \in H$$

then the equivalence class can be denoted by left cosets

$$[a] = \{g \in G | a \sim_H g\} = aH$$

and the quotient set (it may not be a group) is denoted by

$$G/H = \{aH | a \in G\}$$

and the quotient map is

$$\pi : G \rightarrow G/H, \quad g \mapsto gH$$

if the quotient map furthermore preserves the group structure, i.e. it is a group homomorphism, then we expect for any $g, h \in G$, $\pi(gh) = \pi(g)\pi(h)$, i.e.

$$ghH = gHhH$$

a sufficient condition here is that $hH = Hh$ for any $h \in G$, that means H is a **normal subgroup**. Hence we can define the quotient group as following:

Definition 1.2. Let G be a group and H be a normal subgroup of G , the **quotient group** of G with respect to H is defined as the set G/H with the multiplication

$$(aH)(bH) := (ab)H$$

for any $a, b \in G$, and the group morphism $\pi : G \rightarrow G/H, g \mapsto gH$ is called the **canonical morphism**.

The group is a symmetric object, and the equivalence relation given by subgroup is a little special, the partition of G given by H is uniform:

We notice that the translation $L_g : G \rightarrow G, x \mapsto gx$ is a bijection (not a group morphism unless $g = e$), so the restriction of L_g on any subgroup implies $gH = L_g(H)$, that means any two left cosets (equivalence class) have the same **cardinality** as H , in particular, if G is a finite group, then $|H|$ divides $|G|$, this is the **Lagrange's theorem**.

Like what we do in topology and set theory, we can also conclude a universal property for group:

Theorem 1.5 (UPQ-GRP).

Let G and K be two groups, H be a normal subgroup of G , and $\varphi : G \rightarrow K$ be a surjective group morphism, then there is a unique group isomorphism $\bar{\varphi} : G/H \rightarrow K$ such that $\varphi = \bar{\varphi} \circ \pi$, where $\pi : G \rightarrow G/H$ is the canonical morphism.

Proof. By UPQ-SET, there is a unique bijection $\bar{\varphi}$ such that $\varphi = \bar{\varphi} \circ \pi$, now we will prove that $\bar{\varphi}$ is a group isomorphism. Take any $aH, bH \in G/H$, then

$$\bar{\varphi}((aH)(bH)) = \bar{\varphi}((ab)H) = \varphi(ab) = \varphi(a)\varphi(b) = \bar{\varphi}(aH)\bar{\varphi}(bH)$$

so $\bar{\varphi}$ is a group morphism, so we finish the proof. □

2 Preliminary

2.1 Compact and Hausdorff space

Definition 2.1. Let $(X, \mathcal{T}) \in \mathbf{Top}$

- A family of open sets $\{U_i\}_{i \in I}$ is called an **open cover** of X if $X = \bigcup_{i \in I} U_i$; If $J \subset I$, the subfamily $\{U_j\}_{j \in J}$ is called a **subcover** of X if it is also an open cover of X .
- X is called a **compact space** if every open cover of X has a finite subcover.

Compactness is a nice property in topology, it is a **intrinsic** property about the topological space itself, it shows a type of "boundedness" and "finiteness" of the space in general. In mathematics, intrinsic property is a property independent of the embedding of the object, it will not change under different views.

Proposition 2.1. *Let $X \in \mathbf{Top}$ be a topological space, and $Y \subset X$ be a subspace of X with the induced topology, then a subset of Y is compact if and only if it is compact in X .*

Proof. Let $C \subset Y$ be a compact subset, then for any open cover $\{U_i\}_{i \in I}$ of Y , we can find a finite subcover $\{U_{i_j}\}_{j=1}^n$ such that $C \subset \bigcup_{j=1}^n U_{i_j}$. Since $U_{i_j} \cap Y$ is open in Y and covers C , we can find a finite subcover of C in X , thus C is compact in X . \square

There are some other properties about compact space, it is very basic but useful, it is something about stability under different operations of set.

Proposition 2.2. *Let $X \in \mathbf{Top}$*

- (1) *$A \subset X$ is closed, then it is compact.*
- (2) *Finite union of compact subsets is compact.*
- (3) *Finite intersection of compact subsets is compact.*
- (4) *Finite product of compact spaces is compact.*

Proof.

\square

Remark 2.1. Notice the restriction of finiteness is important here. For (2), we can see that $\mathbb{R} = \bigcup_{n \in \mathbb{N}} [-n, n]$ but \mathbb{R} is not compact; for (3), an example is $(0, 1] = \bigcap_{n \geq 1} [\frac{1}{n}, 1]$, here the countable intersection of compact sets is not compact, but it can hold if the sequence of sets satisfies some condition, we will talk about it later; for (4), the infinite product of compact spaces is compact in the sense of box topology, but the proof is not easy, we will discuss it in the last.

Another important property of compact is the stability under continuous map, a famous result in analysis is **Weierstrass theorem**: a continuous function on a closed interval can always attain its maximum and minimum, it can be generalized to topology as following:

Proposition 2.3. *Let $X, Y \in \mathbf{Top}$ be two topological spaces, and $f : X \rightarrow Y$ be a continuous map, if X is compact, then $f(X)$ is also compact.*

Proof. □

Remark 2.2. The inverse of the statement is not true, i.e. if $A \subset Y$ is compact, then $f^{-1}(A)$ is not necessarily compact, for example consider the constant map $f : \mathbb{R} \rightarrow \mathbb{R}, x \mapsto 0$, but it can not show the natural reason of the failure.

Let us review the definition of continuous map: a map $f : X \rightarrow Y$ is continuous if for any open set $U \subset Y$, $f^{-1}(U)$ is open in X . Now if we just have a map f and a topological space (Y, \mathcal{T}_Y) , then we can define a topology on X by f as following:

$$\mathcal{T}_f := \{f^{-1}(U) \mid U \in \mathcal{T}_Y\}$$

It is called the **pullback topology** (PLS verify), it is clearly the smallest topology such that f is continuous. So by this view, we can rewrite the definition of the continuous map as following:

Definition. A map $f : X \rightarrow Y$ is continuous if the topology on X is finer than the pullback topology \mathcal{T}_f , i.e. $\mathcal{T}_X \supset \mathcal{T}_f$.

Hence we can conclude the reason: if a topology is very fine (like discrete topology), then a subset will be difficult to be compact, but the continuous map says that the topology on X will be at least fine as the pullback topology, so the inverse image of a compact set may not be compact if the pullback is very fine.

However, compactness is not a sufficient condition in many cases. For example, we always talk about the compact set in a metric space, but not all the topological space is metrizable, so another topological properties is needed here.

Definition 2.2. A topological space (X, \mathcal{T}) is called a **Hausdorff space** if for any two different points $x, y \in X$, there are two open sets $U, V \in \mathcal{T}$ such that

$$x \in U, y \in V, U \cap V = \emptyset$$

A typical example of non-Hausdorff space is the a two-point space:

$$X = \{a, b\}, \quad \mathcal{T} = \{X, \emptyset, \{a\}\}$$

Intuitively, it can be drawn by venus graph:

图 1: A non-Hausdorff space

Hausdorff space is a nice axiom to ensure the separation of points such that limit can be defined uniquely in the space, it is the topic we will discuss in other section, here we just see how hausdorff space interact with compact space:

Proposition 2.4. *Let $X \in \mathbf{Top}$*

- (1) *$A \subset X$ is compact and X is Hausdorff, then A is closed.*
- (2) *Y is a compact subspace of a Hausdorff space X , then the subset of Y is compact if and only if it is closed in X .*
- (3) *$f : X \rightarrow Y$ is a continous bijection, X is compact and Y is Hausdorff, then f is a homeomorphism.*

Proof. □

Remark 2.3. (1) and (2) is the classic result in metric space, but generally it need the Hausdorff condition, otherwise it can fail, for example consider the non-Hausdorff space just now, the singleton $\{b\}$ is compact but not closed.

(3) is a very useful result to verify whether a continuous bijection is a homeomorphism or not, for example in UPQ-TOPO, if we add that Y is Hausdorff, then \bar{f} is furthermore a homeomorphism if the quotient space is compact.

As we mentioned just now, the finite intersection of compact sets is compact, but the countable intersection is not necessary compact, we can add some condition now:

Proposition 2.5 (Nested sequence).

Let $X \in \mathbf{Top}$, and $\{C_n\}_{n \in \mathbb{N}}$ be a decreasing sequence of non-empty compact subsets of X , then the intersection $\bigcap_{n \in \mathbb{N}} C_n$ is non-empty and compact.

Proof. □

Corollary 2.6. *Real number system is complete.*

Proof. □

Remark 2.4. An famous example of nested sequence is the **Cantor set**, it is a typical fractal set with uncountable points but zero measure, it can be constructed by removing the open middle third interval of $[0, 1]$ recursively:

$$C = \bigcap_{n \geq 0} C_n$$

with $C_0 := [0, 1]$ and $C_n := \frac{C_{n-1}-1}{3} \cup (\frac{2}{3} + \frac{C_{n-1}}{3})$ for $n \geq 1$. The figure below shows the construction:

图 2: Construction of Cantor set

Clearly, by the nested sequence proposition, the cantor set is non-empty and compact. It is zero measure by the monotone convergence of measure:

$$m(C) = m(\lim_N \bigcap_{n=0}^N C_n) = \lim_N m(C_N) = \lim_N \frac{2^N}{3^N} = 0$$

And the set is uncountable, it is not so easy to prove, but roughly speaking,

$$C = \{x \in [0, 1] \mid [x]_3 = 0.a_1a_2a_3\dots \text{ for some } a_i \in \{0, 2\}\}$$

every points in cantor set can be represented by a ternary decimal with only 0 and 2, and such a set is uncountable with cardinality 2^{\aleph_0} (PLS see more details in measure theory).

Tychonoff's theorem*

The last part of this section is to clarify the compactness of arbitrary product of compact spaces, it is a useful result in analysis (less so to geometry).

The first thing is to rigorous the definition of product topological space, in the case of finite the definition is natural, but in the case of infinite, we need to be careful. If we copy the definition of finite product, let $\{X_i\}_{i \in I}$ be a family of topological spaces, then the topology on $\prod_{i \in I} X_i$ is defined as

$$\mathcal{T} = \left\{ \prod_{i \in I} U_i \mid U_i \text{ is open in } X_i \right\}$$

Example 2.1. We consider the product space $([0, 1]^{\mathbb{N}}, \mathcal{T})$, we can prove that the space is not compact under above topology:

Take an open cover $\mathcal{O} = \{U_0, U_1, U_2, \dots\}$ where

$$U_0 = \{(a_1, a_2, \dots) \mid a_i < \frac{1}{2}, \quad i \geq 1\}$$

and for any $k \geq 1$,

$$U_k = \{(a_1, a_2, \dots) \mid a_k > \frac{1}{4}\}$$

We notice that if we want to choose a subcover from \mathcal{O} , then U_0 must be chosen, otherwise the point $(0, 0, 0, \dots)$ can not be covered.

Suppose that we have chosen a finite subcover $\{U_0, U_{a_1}, \dots, U_{a_l}\}$ then we can take some $k \notin \{a_1, \dots, a_l\}$, then we construct a point a with $a_k = 1$ and other coordinates equal to 0, then the point a can not be covered by the finite subcover, so we finish the proof.

It shows that the above topology is too fine to ensure the compactness of product space, so we need to modify the definition of product topology. The universal properties of product space can help us to choose the right topology, for any product set $\prod_{i \in I} X_i$ we have a natural projection map

$$\pi_k : \prod_{i \in I} X_i \rightarrow X_k, \quad (x_i)_{i \in I} \mapsto x_k$$

In language of category, we expect the projection will be a morphism in **Top**, that means the projection should be continuous, hence the topology on the product set should be at least fine as the pullback topology induced by π_k :

$$\mathcal{T}_k := \{\pi_k^{-1}(U) | U \text{ is open in } X_k\}$$

In detail, $\pi_k^{-1}(U) = \prod_{i \in I} Y_i$ With

$$Y_k = U, \quad Y_i = X_i \text{ for } i \neq k$$

And we expect all i -projections are continuous, so the smallest topology will be generated by choosing $\bigcup_{i \in I} \mathcal{T}_i$ as the basis for topology, so we can get a more rough topology than before, and we conclude them by a formal definition:

Definition 2.3. Let $(X_i, \mathcal{T}_i) \in \mathbf{Top}$, and $i \in I$ a non-empty index set.

-The product topology on the product set $\prod_{i \in I} X_i$ is defined by

$$\mathcal{B} := \left\{ \prod_{i \in J} U_i \times \prod_{i \in I \setminus J} X_i \mid J \subseteq I \text{ finite}, U_i \in \mathcal{T}_i \right\}$$

- The box topology on the product set is defined by

$$\mathcal{B}_{box} := \left\{ \prod_{i \in I} U_i \mid U_i \in \mathcal{T}_i \right\}$$

Just remind that the product topology is rougher than box topology, and it is the smallest topology such that all projections are continuous maps. The above example shows that the box topology can not keep the compactness of product space. **In particular, the product topology is equal to box topology when the product is finite.**

Another thing needed is an equivalent statement of compactness.

Definition. A collection of subsets $\{C_i\}_{i \in I}$ in a topological space X is said to have the **FIP (finite intersection property)** if for any finite subset $J \subset I$, $\bigcap_{j \in J} C_j \neq \emptyset$.

In a short word, *FIP* means that any finite intersection of subcollection is nonn-empty.

Proposition 2.7 (FIP-COMPACT).

Let $X \in \mathbf{Top}$, then X is compact if and only if for any collection of closed subsets $\{C_i\}_{i \in I}$ with properties FIP, the intersection $\bigcap_{i \in I} C_i$ is non-empty.

Proof. □

Remark 2.5. A direct corollary is the nested sequence propostion 2.5, because a decreasing sequence of non-empty closed subsets obviously has the property FIP.

Theorem 2.8 (Tychonoff's theorem).

Let $\{X_i\}_{i \in I}$ be a family of compact spaces, then the product space $\prod_{i \in I} X_i$ with product topology is also compact.

2.2 Topological axioms

The topology determines the structure of the space, if we have a topological space we can naturally study its structure by the open sets. Conversely, if we want to construct a topological space, we need to define a topology by choosing some open sets, usually it is difficult to write all open sets down directly, we need a collection like "base" for vector space.

Definition 2.4. Let X be a non-empty set, a collection $\mathcal{B} \subset \mathcal{P}(X)$ is called a **basis for a topology** on X if

- (1) For any $x \in X$, there is at least one basis element $B \in \mathcal{B}$ such that $x \in B$.
(equivalently, $\bigcup_{B \in \mathcal{B}} B = X$)
- (2) If x belongs to the intersection of two basis elements $B_1, B_2 \in \mathcal{B}$, then there is a basis element $B_3 \in \mathcal{B}$ such that $x \in B_3 \subseteq B_1 \cap B_2$.
(equivalently, finite intersection of basis elements is in the basis.)

The topology \mathcal{T} generated by \mathcal{B} is defined as

$$\mathcal{T} := \{U \subset X | \forall x \in U, \exists B \in \mathcal{B} \text{ such that } x \in B \subseteq U\}$$

i.e. the open set is of the form of union of basis elements.

We need to verify that the axiom of topology generated by basis:

(1) $X \in \mathcal{T}$ since by (1) of basis definition, we can find a basic open sets $B_x \in \mathcal{B}$ for any x , then

$$X = \bigcup_{x \in X} B_x$$

satisfy the definition of open sets. For empty-set, it holds formally by

$$\emptyset = \bigcup_{x \in \emptyset} B_x$$

However, no points in empty-set implies that the condition is vacuously true, so $\emptyset \in \mathcal{T}$.

(2) For any $U, V \in \mathcal{T}$, and any $x \in U \cap V$, by the definition of open sets, there are basis elements $B_1, B_2 \in \mathcal{B}$ such that

$$x \in B_1 \subseteq U \quad \text{and} \quad x \in B_2 \subseteq V$$

Then $B_1 \cap B_2$ is a basis element containing x and is contained in $U \cap V$, thus $U \cap V \in \mathcal{T}$.

(3) For any collection of open sets $\{U_i\}_{i \in I} \subset \mathcal{T}$, and any $x \in \bigcup_{i \in I} U_i$, then there is some $j \in I$ such that $x \in U_j$, by the definition of open sets, there is a basis element $B \in \mathcal{B}$ such that

$$x \in B \subseteq U_j \subseteq \bigcup_{i \in I} U_i$$

thus $\bigcup_{i \in I} U_i \in \mathcal{T}$.

A typical example of basis is the standard basis of \mathbb{R} :

$$\mathcal{B} = \{(a, b) \mid a < b, a \text{ and } b \in \mathbb{Q}\}$$

It is easy to verify that \mathcal{B} satisfies the two conditions of basis, and the topology generated by \mathcal{B} is the standard topology on \mathbb{R} . Generally, any **metric space** (X, d) has a topology base which generates the metric topology:

$$\mathcal{B} = \{B(x, r) \mid x \in X, r > 0\}$$

where $B(x, r) = \{y \in X \mid d(x, y) < r\}$ is the open ball with center x and radius r , hence sometimes we **call open ball as basic open set** in metric space.

Countable axiom

In analysis, we always use the tool of sequences: we take a voisinage of a point, then choose another point in the voisinage, and repeat this process to the smaller voisinage, and so on, finally we get a sequence $\{a_n\}_{n \in \mathbb{N}}$ which converges to the point and a sequence

of voisinage $\{V_n\}_{n \in \mathbb{N}}$, they are all countable! Hence, at least the topology of the space allows us to choose countable open sets, that is the **motivation** of countable axiom in topology.

Definition 2.5. Let $(X, \mathcal{T}) \in \mathbf{Top}$ be a topological space,

(1) X is called **first-countable** if for any point $x \in X$, there is a countable (local) basis $\mathcal{B}_x = \{B_{x,n}\}_{n \in \mathbb{N}}$ of open sets such that for any open set U containing x , there is some $B_{x,n} \in \mathcal{B}_x$ such that

$$x \in B_{x,n} \subseteq U$$

(i.e. each point has a countable local basis).

(2) X is called **second-countable** if there exists a countable basis for topology \mathcal{T} .

Clearly, second-countable implies first-countable, because for any $x \in X$, we can just choose the local basis $\mathcal{B}_x = \mathcal{B}$. Conversely, first-countable does not imply second-countable, for example consider the discrete topology on \mathbb{R}

$$\mathcal{T}_d = \mathcal{P}(\mathbb{R})$$

it is first-countable since we can choose $\mathcal{B}_x = \{\{x\}\}$ for any $x \in \mathbb{R}$, but it is not second-countable since the smallest open set containing x is $\{x\}$ itself, so at least

$$\{\{x\} \mid x \in \mathbb{R}\} \subset \mathcal{B}$$

which implies that \mathcal{B} is uncountable.

Another example is **cofinite topology** on \mathbb{R}

$$\mathcal{T}_c = \{U \subset X \mid \#X \setminus U < +\infty\} \cup \{\emptyset, \mathbb{R}\}$$

We can prove that it is neither first-countable nor second-countable (**Verify!**).

In a short word, countable axiom determine **whether we can study convergence using sequences** (instead of the more general notions of nets or filters). Second-countable axiom can implies other nice type of space as following:

Proposition 2.9. Let $X \in \mathbf{Top}$ be a second-countable space, then

(1) X is **separable**, i.e. there is a countable dense subset $D \subset X$.

(2) X is **Lindelöf**, i.e. every open cover of X has a countable subcover.

Proof. (1) Since X is second-countable, we can find a countable basis \mathcal{B} for the topology \mathcal{T} . For each $B \in \mathcal{B}$, we can find a point $x_B \in B$. Then the set $D = \{x_B \mid B \in \mathcal{B}\}$ is countable and dense in X .

(2) Let $\{U_i\}_{i \in I}$ be an open cover of X . For each $x \in X$, we can find a basis element $B_x \in \mathcal{B}$ such that $x \in B_x \subseteq U_i$ for some $i \in I$. Since \mathcal{B} is countable, we can extract a countable subcover $\{U_{i_n}\}_{n \in \mathbb{N}}$ that covers X . \square

A nice equivalence can be concluded in metric space:

Corollary 2.10. *In metric space*

$$\text{second-countable} \iff \text{separable} \iff \text{Lindelöf}$$

Proof. outline:

(a) Lindelöf \implies separable in metric space

We consider the n-open cover

$$\mathcal{U}_n = \{B(x, 1/n) \mid x \in X\}$$

By Lindelöf property, each n-open cover has a countable subcover

$$\mathcal{V}_n = \{B(x_{n,k}, 1/n) \mid k \in \mathbb{N}\}$$

then we can choose a subset of X as

$$D = \{x_{n,k} \mid n, k \in \mathbb{N}\}$$

then we can prove that D is dense in X .

(b) separable \implies second-countable in metric space

It is similar to find a countable basis for topology in \mathbb{R} using the dense subset \mathbb{Q} . Suppose D is a countable dense subset of X , then we can choose

$$\mathcal{B} = \{B(d, q) \mid d \in D, q \in \mathbb{Q}\}$$

then we can prove it is a basis for topology, and verify the topology generated by \mathcal{B} is same as the metric topology.

(c) conclude by the above proposition. \square

Separation Axiom

The motivation of separation axiom is to ensure the separation of points or sets using open sets, it is useful to define limit and continuity in topology. We can define the sequence of limit in topology instead of $\epsilon - \delta$ language as following:

Definition. Let $(X, \mathcal{T}) \in \mathbf{Top}$ be a topological space, and $\{x_n\}_{n \in \mathbb{N}}$ be a sequence in X , a point $x \in X$ is called a **limit** of the sequence (or **converges** to x) if for any open set U containing x , there is some $N \in \mathbb{N}$ such that for any $n \geq N$, $x_n \in U$.

We can construct an example such that a sequence has different limits:

$$X = \{0, 1, 2\}, \quad \mathcal{T} = \{\emptyset, X, \{2\}, \{1, 2\}\}$$

In this case, we consider the constant sequence $x_n = 2$, then we can find that both 1 and 2 are limits of the sequence (**checking the definition!**). Hence it is necessary to clasify the space to aviod the case like this.

Another motivation is from the view of outer measure. We want to define the measure of a set A by the infimum of the measures of open sets containing A :

$$m^*(A) = \inf\{m(U) | U \supset A, U \text{ is open}\}$$

where m is a measure defined on basic open sets. Now if $A = A_1 \cup A_2$ a disjoint union of two sets, and we hope that

$$m^*(A) = m^*(A_1) + m^*(A_2)$$

then clearly here we must allow the existence of two disjoint open sets U_1, U_2 such that $A_1 \subset U_1$ and $A_2 \subset U_2$, otherwise the equality can fail, the correspondece to this requirement is the normal space in topology.

Definition 2.6. Let $(X, \mathcal{T}) \in \mathbf{Top}$ be a topological space,

(1) X is called a **T0 space** if for any two different points $x, y \in X$, there is an open set $U \in \mathcal{T}$ such that

$$x \in U, y \notin U \quad \text{or} \quad y \in U, x \notin U$$

(2) X is called a **T1 space** if for any two different points $x, y \in X$, there are two open sets $U, V \in \mathcal{T}$ such that

$$x \in U, y \notin U \quad \text{and} \quad y \in V, x \notin V$$

(3) X is called a **Hausdorff space (T2 space)** if for any two different points

$x, y \in X$, there are two open sets $U, V \in \mathcal{T}$ such that

$$x \in U, y \in V, U \cap V = \emptyset$$

(4) X is called a **regular space (T3 space)** if it is a $T1$ space such that for any closed set $C \subset X$ and any point $x \notin C$, there are two open sets $U, V \in \mathcal{T}$ such that

$$x \in U, C \subset V, U \cap V = \emptyset$$

(5) X is called a **normal space (T4 space)** if it is a $T1$ space such that for any two disjoint closed sets $C_1, C_2 \subset X$, there are two open sets $U, V \in \mathcal{T}$ such that

$$C_1 \subset U, C_2 \subset V, U \cap V = \emptyset$$

Remark 2.6. (1) In above definition, we have a good chain of implications:

$$T4 \implies T3 \implies T2 \implies T1 \implies T0$$

it reflects the strength of separation axiom.

(2) In above definition, The condition of $T1$ space in $T3$ and $T4$ can not be omitted (even if it satisfies automatically in many cases), otherwise we can not get above implications, for example consider a trivial non-Hausdorff space

$$X = \{a, b\}, \quad \mathcal{T} = \{\emptyset, X\}$$

but we notice that it is normal space since the unique closed sets are \emptyset and X , and trivially we can find two disjoint open sets containing them (**it is just a stupid logical game**), i.e. \emptyset and X .

(3) The most used separation axiom is Hausdorff space, because it is easy to verify and have many good properties. **An equivalent statement** of Hausdorff space is that the diagonal set

$$\Delta = \{(x, x) | x \in X\} \subset X \times X$$

is closed in the product space $X \times X$ (**verify!**).

(4) Any **metric space** is normal space, so it is also $T3, T2, T1, T0$ space.

It is not free to get a space with strong separation, we can add some condition such that we can get a nice space:

Proposition 2.11. *Let $X \in \mathbf{Top}$ be a topological space, then*

- If X is $T3$ and second-countable, then X is $T4$.

- If X is T_2 and compact, then X is T_4 .

Proof. see Munkres' Topology book (section 32). \square

It is important to see the stability of separation axiom under different operations, it is easy to verify.

Proposition 2.12. *The stability of separation axiom:*

(1-subspace) any subspace of a T_i space is still a T_i space for $i = 0, 1, 2, 3$.

(2-finite product) the finite product of T_i spaces is still a T_i space for $i = 0, 1, 2, 3$.

(3-product) The any product of T_i spaces is still a T_i space for $i = 0, 1, 2$.

(3-map) Let $f : X \rightarrow Y$ be a continuous bijection and Y is a T_i space for $i = 0, 1, 2, 3, 4$, then X is still a T_i space.

Proof. Just some verification... \square

Remark 2.7. (1) Normal space is not stable in above proposition, an counterexample is **Tychonoff plank**.

(2) The product of two normal spaces may not be normal, an counterexample is **Sorgenfrey plane**. We consider the Sorgenfrey line (lower limit topology) \mathbb{R}_l generated by basis

$$\mathcal{B} = \{[a, b) | a < b\}$$

It is normal because the topology is finer than standard topology:

$$(a, b) = \bigcup_{x \in (a, b)} [x, b)$$

but the product space \mathbb{R}_l^2 is not normal.

(3) Many examples can be found in 拓扑空间与线性拓扑空间中的反例 by 汪林.

(4) the separation can not be transitive like compactness and connectedness, i.e. $f(X)$ may not be T_i space even if X is T_i space. It is reasonable since continuous map implies that the topology of X is finer than the pullback topology induced by f , it gives no information about the topology of image space.

Finally, we will conclude some classic result in analysis, and we will see that how separation axiom works in them: In metric spaces

(1) a sequence has at most one limit.

(2) $x \in \overline{A}$ iff there is a sequence $\{a_n\}_{n \in \mathbb{N}}$ of A such that a_n converges to x .

(3) A function $f : X \rightarrow Y$ is continuous iff for any sequence $\{x_n\}_{n \in \mathbb{N}}$ converging to x , the sequence $\{f(x_n)\}_{n \in \mathbb{N}}$ converges to $f(x)$.

In general, (1) holds if X is **Hausdorff space**, (2) and (3) hold if X is **first-countable** space.

3 Topological group

3.1 Definition

Group and Topological space is two different objects, group is algebraic structure, topological space is geometric structure, but it is not strange to combine them together.

Definition 3.1. A **topological group** is a object (G, \mathcal{T}, \cdot) such that

- (G, \cdot) is a group
- (G, \mathcal{T}) is a topological space
- The group structure is compatible with topological structure, i.e. multiplication

$$m : G \times G \rightarrow G, \quad (x, y) \mapsto x \cdot y$$

and inverse

$$i : G \rightarrow G, \quad x \mapsto x^{-1}$$

are continuous maps.

Let us see some examples of topological groups

Example 3.1.

- (1) \mathbb{R}^n with addition and standard topology is a topological group.
- (2) $\mathbb{S}^1 = \{z \in \mathbb{C} \mid |z| = 1\}$ with multiplication and subspace topology of \mathbb{C} is a topological group.
- (3) The torus T can be seen as the product of two topological groups $\mathbb{S}^1 \times \mathbb{S}^1$, by the universal property of product topology, T is also a topological group.
- (4) Any discrete group with discrete topology is a topological group.
- (5) $GL(n, \mathbb{R})$ with multiplication and subspace topology of \mathbb{R}^{n^2} is a topological group.

we first prove some properties of topological group, the results are not difficult, but it is always useful.

Proposition 3.1. *Let G be a topological group and H be a subgroup of G , then*

(1-translation) For any $g \in G$, the left-translation $L_g : G \rightarrow G, x \mapsto g \cdot x$ and

right-translation $R_g : G \rightarrow G, x \mapsto x \cdot g$ are homeomorphisms.

(2-open) If H is open, then H is closed and G/H is discrete.

(3-Hausdorff)

$$G \text{ is Hausdorff} \iff \{e\} \text{ is closed.}$$

$$G/H \text{ is Hausdorff} \iff H \text{ is closed in } G.$$

(4-homogeneous) If G is connect, then any voisinage of $\{e\}$ can generate the group.

(5-CC) Let G_0 be the connected component of G containing e , then G_0 is a closed normal subgroup of G , and any connected component of G is homeomorphic to G_0 .

Proof.

□

Remark 3.1. Translation is very important in topological group, group is a object with symmetry and translation is a way to keep symmetry. For example, let x, y be two different points in G , then the translation $L_{yx^{-1}}$ is a homeomorphisms which maps x to y , therefore each point of G share the same topological stucture, so the local property is same as golbal poerperty, that means topological group is a **homogeneous space**.

the fundamental theorem of group homeomorphisms can be extended to topological group, in the discussion of topological group, we hope the map between two objects can preserve both two structures, that means the map is both a morphism of group and a continous map.

Example 3.2. We consider two topological groups: the first is \mathbb{R} with addition and standard topology, the second is \mathbb{S}^1 with multiplication and subspace topology of \mathbb{C} (or \mathbb{R}^2). We define a map

$$\varphi : \mathbb{R} \rightarrow \mathbb{S}^1, \quad x \mapsto e^{2\pi i x}.$$

(1) φ is a surjective group morphism with $\ker \varphi = \mathbb{Z}$.

(2) By UPQ-GRP, there is a unique group isomorphism $\bar{\varphi} : \mathbb{R}/\mathbb{Z} \rightarrow \mathbb{S}^1$ such that

$$\mathbb{R}/\mathbb{Z} \cong \mathbb{S}^1$$

(3) By UPQ-TOPO, $\bar{\varphi}$ is also a continous bijection since φ is continous.

(4) Notice that \mathbb{S}^1 is a Hausdorff space, \mathbb{R}/\mathbb{Z} is compact (verify!) so $\bar{\varphi}$ is automatically a homeomorphism.

We define the **isomorphism** between two topological groups are an application which is both a **group isomorphism** and a **homeomorphism**, the above examples shows that \mathbb{R}/\mathbb{Z} and \mathbb{S}^1 are isomorphic as topological groups, with the similar techniques we can prove that $SO(2)$ is also isomorphic to \mathbb{S}^1 as a topological group. We can generalized the result to be a so-called universal properties:

Theorem 3.2 (UPQ-TGRP).

Let G and K be two topological groups, and $\varphi : G \rightarrow K$ be a topological group morphism (i.e. continuous morphism of group), then there is a unique continuous morphism of groups $\bar{\varphi} : G/\ker \varphi \rightarrow K$ such that the digram commutes

$$\begin{array}{ccc} G & \xrightarrow{\varphi} & K \\ \pi \downarrow & \nearrow \exists! \bar{\varphi} & \\ G/\ker \varphi & & \end{array}$$

furthermore, if the following conditions hold:

- (1) φ is surjective,
- (2) K is Hausdorff,
- (3) $G/\ker \varphi$ is compact,

then $\bar{\varphi}$ is an isomorphism of topological groups.

Neighborhood system

As we have mentioned before, topological group is a homogeneous space, so the local topology at one point can be translated to generate the global topology, for some convenience, we always study the local topology at identity of the group.

Formally, for any group G we define the **neighborhood system** (at x) to be the collection of subsets containing x , denoted by \mathcal{V}_x :

$$\forall A \in \mathcal{V}, \quad e \in A \wedge A \subset G$$

Hence we can induce a topology on G by neighborhood system (i.e. determine the open voisinage of identity).

Proposition 3.1. Let G be a group with \mathcal{V}_e as the neighborhood system at identity e , if \mathcal{V}_e satisfies the following conditions:

- 1. For any $U, V \in \mathcal{V}_e$, there exists $W \in \mathcal{V}_e$ such that

$$W \subset U \cap V.$$

2. If $a \in U \in \mathcal{V}_e$, then there exists $V \in \mathcal{V}_e$ such that

$$Va \subset U.$$

3. For each $U \in \mathcal{V}_e$, there exists $V \in \mathcal{V}_e$ such that

$$V^{-1}V \subset U.$$

4. For each $U \in \mathcal{V}_e$ and each $x \in G$, there exists $V \in \mathcal{V}_e$ such that

$$x^{-1}Vx \subset U.$$

then there exist a unique topology \mathcal{T} such that \mathcal{V}_e is the set of all open voisinage of e , and (G, \mathcal{T}) is a topological group.

Proof. The topology \mathcal{T} is uniquely defined by translation:

$$\mathcal{B} = \{gU \mid g \in G, U \in \mathcal{V}_e\}$$

we just need to prove that \mathcal{B} is the topology basis. Notice the condition (1) and (2) ensure that \mathcal{B} generates a topology, the condition (3) is the requirement of continuity of multiplication and inverse; finally, the condition (4) is obligator for non-abelian group to ensure the continuity. \square

In partiucular, we can naturally choose subgroup as the element in the system, the condition can be simplified as following:

Corollary 3.2. *Let G be a group with \mathcal{U} as a collection of subgroups of G , if \mathcal{U} satisfies the following conditions:*

1. For any $U, V \in \mathcal{U}$, there exists $W \in \mathcal{U}$ such that

$$W \subset U \cap V.$$

2. For each $U \in \mathcal{U}$ and each $x \in G$, there exists $V \in \mathcal{U}$ such that

$$x^{-1}Vx \subset U.$$

then there exist a unique topology \mathcal{T} such that \mathcal{U} is a basis of open voisinage of e , and (G, \mathcal{T}) is a topological group.

Here are some classic examples of topological groups constructed by neighborhood system:

Example 3.3. We consider the usual topology on \mathbb{Q} , then the completion of \mathbb{Q} is just \mathbb{R} , it is another method to construct real number (see in Bourkabi's book). We review that we always write the viosinage of 0 as the form of $(-\varepsilon, \varepsilon)$, which motivates us to consider the system of subgroup:

$$\mathcal{U} = \left\{ \frac{1}{n}\mathbb{Z} \mid n \in \mathbb{N}^* \right\}$$

pay attention to the choices here! We can not take $n\mathbb{Z}$ to be an open set (consider it in \mathbb{R} , it is closed and not open). Then we can verify the topology induced by \mathcal{U} is just the subspace topology induced by \mathbb{R} , i.e. it induces a usual absolute value on field \mathbb{Q} :

$$|x|_\infty = \begin{cases} x & x \geq 0 \\ -x & x \leq 0 \end{cases}$$

It is natural to ask that can we define other topological stucture on \mathbb{Q} such that we can get other different completion? The answer is yes, and a classic example is the **p -adic number field**.

Example 3.4. We fix a prime number p and then we can define a subgroup

$$\mathbb{Z}_{(p)} = \left\{ \frac{m}{n} \mid m, n \in \mathbb{Z}, p \nmid n \right\}$$

and we let $\mathcal{U} = \{p^t \mathbb{Z}_{(p)} \mid t \in \mathbb{Z}\}$ to be the collection of subgroups, which generates an unique toplogy (verify!). Notice that we have a unique chain in the system:

$$\dots p^2 \mathbb{Z}_{(p)} \subset p \mathbb{Z}_{(p)} \subset \mathbb{Z}_{(p)} \subset p^{-1} \mathbb{Z}_{(p)} \subset p^{-2} \mathbb{Z}_{(p)} \subset \dots$$

motivates from the above example, we consider each subgroup gives a method to measure the size of an elemnt is some sense, for example we consider the following number when $p = 3$:

$$1, \quad 4, \quad \frac{1}{2}, \quad \frac{2}{5}$$

they are all in $\mathbb{Z}_{(p)}$, and we consider the distance of them to 0 can be bounded by α (consider $(-\varepsilon, \varepsilon)$ gives the set of all elements with distance to 0 less than ε), and then we consider some other numbers:

$$\frac{1}{3}, \quad \frac{2}{3}, \quad \frac{7}{6}$$

they are all in $\frac{1}{3}\mathbb{Z}_{(p)}$ but not in $\mathbb{Z}_{(3)}$, so we can think that their distance to 0 is bouned by β , and it is natural to give a realtion $\alpha < \beta$, which motivates us to give

a new method to consider the metric on \mathbb{Q} by consider the local factorization of p .

Hence we can define something to denote α and β just now:

$$v_p : \mathbb{Z} - \{0\} \rightarrow \mathbb{N}, \quad m \mapsto \max\{k : p^k | m\}$$

for example $v_3(6) = 2$, $v_3(-2) = 0$. Then the method of measuring can be extended to \mathbb{Q} as following:

$$v_p : \mathbb{Z} - \{0\} \rightarrow \mathbb{Z}, \quad \frac{m}{n} \mapsto v_p(m) - v_p(n)$$

And we make a convention that $v_p(0) = +\infty$, it is called **p-adic valustion**. for example $v_3(\frac{1}{3}) = -1$, $v_3(\frac{9}{2}) = 2$. Then we can get a measure of number

$$p^k \mathbb{Z}_{(p)} \iff \{x \in \mathbb{Q} \mid v_p(x) \geq p^k\}$$

but a question occurs here is that $v_3(1) = 0$ and $v_3(\frac{1}{3}) = -1$, as what we discussed just now, actually we hope the measure of 1 should be less than the measure of $\frac{1}{3}$ (here $0 > -1$), hence the valuation v_p can not be treated as the absolute value directly, hence we modify it as following:

$$|\cdot|_p : \mathbb{Q} \rightarrow \mathbb{R}_+, \quad x \mapsto \frac{1}{e^{v_p(x)}}$$

the convention just now forces $|0|_p = 0$, and again we can get a clear measure of numbers:

$$x \in p^k \mathbb{Z}_{(p)} \iff |x|_p \leq e^{-k}$$

hence $|1|_3 < \frac{1}{3}|_3$, which admits our original idea.

Remark 3.2. it is just a short introduction of p-adic number from the view of topological group, and here are something to supplement if to go deeper:

(1) The metric of is induced by the absolute value:

$$d(x, y) = |x - y|_p$$

we can verify that is a **ultrametric (non-archimedean metric)**, i.e. a metric satisfying the strong triangle inequality:

$$d(x, z) \leq \max\{d(x, y), d(y, z)\}, \quad \forall x, y, z \in \mathbb{Q}$$

which induces different analysis structure on \mathbb{Q} .

(2) Same situation with \mathbb{Q} equipped by the usual absolute value, $(\mathbb{Q}, |\cdot|_p)$ is not complete as a metric space, we can complete it to get the **p-adic number field** \mathbb{Q}_p . (The completion process is same with what we do for the real number, and we can prove that the completion is unique up to isometry.)

(3) By **Ostrowski's theorem**, any non-trivial absolute value on \mathbb{Q} is equivalent to either the usual absolute value or some p -adic absolute value. In detail, if $|\cdot|$ is a non-trivial absolute value on \mathbb{Q} , then either there is some $c > 0$ such that

$$|x| = |x|_\infty^c, \quad \forall x \in \mathbb{Q}$$

or there is some prime p and some $c > 0$ such that

$$|x| = |x|_p^c, \quad \forall x \in \mathbb{Q}$$

3.2 Group Action

A group action is a natural language to describe the symmetry of a space, in geometry it refers to the transformation which keeps the structure of the space, in dynamics it refers to the evolution of the system, it is a very useful tool to study a given space and system.

Definition 3.2. Let (G, \cdot) be a group and X be a set, a **group action** of G on X is a map

$$\phi : G \times X \rightarrow X, \quad (g, x) \mapsto g * x$$

such that

(1-identity) for any $x \in X$, $e * x = x$ where e is the identity element of G .

(2-associativity) for any $g, h \in G$ and $x \in X$, $(gh) * x = g * (h * x)$.

Remark 3.3.

If we call the action ϕ as left-action, then we can define the right-action similarly by

$$\phi : X \times G \rightarrow X, \quad (x, g) \mapsto x * g$$

such that it satisfies the similar axioms. One reason to always define action as a left-action is that we always define a group of matrix acting on some geometry object, then it is more natural to write $A \cdot x$ instead of $x \cdot A$.

For notation simplicity, we always $G \curvearrowright X$ to denote a group action of G on X .

Historically, group action is first defined as a group of transformation (maybe Galois), for example we consider the roots of a polynomial equation $p(x) = 0$

$$X = \{x_1, \dots, x_n | f(x_i) = 0\}$$

then consider the set of permutations (i.e. the bijection inside X) S_X , then with the composition of functions, we know that S_X is a group, and it acts on X naturally by

$$\phi : S_X \times X \rightarrow X, \quad (\sigma, x_i) \mapsto \sigma(x_i)$$

That is the original idea of Galois.

Similarly, the definition of action induces a natural map as following: we fix some element $g \in G$, then we can define a map

$$\tau_g : X \rightarrow X, \quad x \mapsto g * x$$

then by the two axioms of group action, we can prove that τ is a bijection from X to X (**verify!**), hence it induces a map from the group to the transformation group of X :

$$\tau : G \rightarrow S_X, \quad g \mapsto \tau_g$$

we can verify that τ is a group morphism (**verify!**).

Conversely, if we have a group morphism from G to S_X , and we denote it by τ , then we can define a group action (**verify!**) of G on X naturally by $g * x := \tau(g)(x)$. Hence we can conclude a **correspondece** as following:

$$\begin{aligned} \{\text{Group action } G \curvearrowright X\} &\longleftrightarrow \{\text{homomorphism } \tau : G \rightarrow S_X\} \\ g * x &\longleftrightarrow \tau(g)(x) \end{aligned}$$

the homomorphism τ is called the **permutation representation** of the group action. It is a basic relation to understand group action from the veiw of pure group theory.

Example 3.5 (Cayley's Theorem). Let (G, \cdot) be a group, we can define a group action of G on itself by left-translation:

$$\phi : G \times G \rightarrow G, \quad (g, x) \mapsto g \cdot x$$

then by the above correspondece, it induces a permutation representation

$$\tau : G \rightarrow S_G, \quad g \mapsto \tau_g$$

where $\tau_g(x) = g \cdot x$. Then the kernel is trival since

$$\ker \tau = \{g \in G \mid g \cdot x = x, \forall x \in G\} = \{e\}$$

then by the first isomorphism theorem of group, we can conclude: **any group is isomorphic to a subgroup of some permuation group.**

Orbit and Stabilizer

Let $G \curvearrowright X$ be a group action with a operation $g * x$, then we can give a partition of X by the following definition:

$$x \sim y \iff \exists g \in G, g * x = y$$

we can check that \sim is indeed an equivalence relation on X (**verify!**) with the class of equivalence called **orbits**:

$$O(x) = \{y \in X \mid x \sim y\} = \{g * x \mid g \in G\}$$

Sometimes we also use $G * x$ (or $G \cdot x$) to denote the orbit of x , and the partition of X is given by a geometrical way:

- In particular, if the orbit of the action is unique, then we say that the orbit is **transitive**, i.e. for any $x, y \in X$, there is some $g \in G$ such that $g * x = y$. Formally, we call a space X as a **G-homogeneous** space if G acts on X transitively.
- In the picture, we can view there are some fixed points, i.e. the orbit of the point has only one point: $G * x = \{x\}$, to reflect the scale of the orbits we invite another concept: for some $x \in X$, the **stabilizer** (or isotropy group) of x is defined by

$$G_x = \{g \in G \mid g * x = x\}$$

it is a subgroup of G (**verify!**), in particular a point x is a fixed point iff $G_x = G$. It is not difficult to find the fact that if the stabilizer is "larger", the the orbit is "smaller", here if G and X is finite, then what we say is just the order, but if they are infinite, then the vocabulary "small" and "large" are vague, **here what i say is juat a feeling**.

- When X is finite, we can conlude the **class equation** by the partition of orbits:

$$|X| = |X_0| + \sum_{\substack{O \in X/\sim \\ |O| > 1}} |O|$$

where X^0 is the set of all fixed points. The equation is powerful in the p-group theory to do some counting.

- We often difine the fixed ponit of the function $f(x)$ as some point a such that $f(a) = a$, it has the sense of stability under the sense of dynamics. In the view of group action, for any tanslation $l_g : x \mapsto g * x$, we can define the fixed point of the function l_g as some point a such that $g * a = a$, hence the set of fixed points

of l_g is just the stabilizer G_a . For example, if we consider group \mathbb{Z} acting on some geometry objects by $n * x = n + x$, then the translation can not fix any point unless the translation is the identity, it shows that the action is not stable at all. Hence in that view, we can define an action to be **free** if any non-trivial translation can not fix any point, or equivalently,

$$\forall x \in G, \quad G_x = \{e\}$$

the stabilizer is always trivial.

Example 3.6. Here are some examples of group action:

(1) Consider permutation group S_n acting on the set $X = \{1, 2, \dots, n\}$ by

$$\phi : S_n \times X \rightarrow X, \quad (\sigma, i) \mapsto \sigma(i)$$

then the action is transitive since for any $i, j \in X$, we can choose $\sigma = (ij)$ such that $\sigma(i) = j$. The action is not free since for any $i \in X$, the stabilizer G_i is the subgroup of S_n which keeps i fixed, it is isomorphic to S_{n-1} .

(2) Consider $\mathbb{R}_{>0}$ acting on $\mathbb{R}^2 - \{0\}$ by multiplication:

$$a * (x, y) := (ax, ay)$$

Then the orbit of (x, y) is the ray line with the same direction with (x, y) , and actually we can see the quotient space $\mathbb{R}^2 - \{0\} / \sim$ as \mathbb{S}^1 , where \sim is the equivalence relation by orbits. The action is actually free (**Verify!**).

(3) Consider $\mathbb{Z}/2\mathbb{Z}$ acting on \mathbb{S}^1 by reflection:

$$0 * (x, y) = (x, y), \quad 1 * (x, y) = (-x, -y)$$

Then the orbit of (x, y) is $\{(x, y), (-x, -y)\}$, and the action is free too. Similarly with (2), we can see the quotient space \mathbb{S}^1 / \sim as \mathbb{RP}^1 , the more details of topology will be discussed later.

(4) Consider a vector space V acting on $F(V)$, where F is a forgetful functor such that $F(V)$ is only seen as a set, then let the action be

$$v * x = x + v$$

If the action is free and transitive, then we say that $F(V)$ is an **affine space** of the vector space V .

(5) We consider the group $SO(2)$ acting on \mathbb{R}^2 by rotation:

$$R_\theta * (x, y) = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$$

the rotation action is free but not transitive, since the orbits are $\{0\}$ and the circles centered at origin.

As we have stated before, the orbit and stabilizer show the performance of the action together, and here is the proposition to reflect the deep relation between them:

Proposition 3.3. *Let $G \curvearrowright X$ be a group action with operation $g * x$, then*

*- For any $x \in X$, the map $\pi : G \rightarrow O(x)$, $g \mapsto g * x$ induces a bijection*

$$\bar{\pi} : G/G_x \rightarrow O(x)$$

- If G is finite and $O(x)$ is finite for some $x \in X$, then

$$|O(x)| = [G : G_x] = \frac{|G|}{|G_x|}$$

Proof. The proof is based on the UPQ-SET, subgroup G_x gives an equivalence relation on G by

$$g_1 \sim g_2 \iff g_1 G_x = g_2 G_x \iff g_1^{-1} g_2 \in G_x$$

then for any $g_1 \sim g_2$, we have $g_1^{-1} g_2 * x = x$ by relation, then by axiom of group action, we have $\pi(g_1) = g_1 * x = g_2 * x = \pi(g_2)$, by universal properties we can conclude a unique map $\bar{\pi} : G/G_x \rightarrow O(x)$ with $\bar{\pi}(gG_x) = g * x$. This map is surjective since π is surjective, and it is injective since for any $g_1, g_2 \in G$ such that $\bar{\pi}(g_1 G_x) = \bar{\pi}(g_2 G_x)$, then $g_1 * x = g_2 * x$, hence $g_2^{-1} g_1 * x = x$, so $g_2^{-1} g_1 \in G_x$, i.e. $g_1 G_x = g_2 G_x$. Therefore $\bar{\pi}$ is a bijection.

The second part is immediately by the Lagrange's theorem. \square

Remark 3.4. Review above example, in (1) we have indeed the equation

$$|S_n/S_{n-1}| = n!/(n-1)! = n = |O(x)|$$

Hence the proposition is reasonable here. In (2) and (3), it refers to an immediate result of the proposition:

Corollary 3.3. *If the action is free, then for any $x \in X$, there exists a bijection*

$$\pi : G \rightarrow O(x), \quad g \mapsto g * x$$

Or we say that each orbit as a G -set is isomorphic to the group. Hence in above two examples, we can say that each orbit is isomorphic to $\mathbb{R}_{>0}$ and $\mathbb{Z}/2\mathbb{Z}$ respectively as G -sets.

Continuous action

Now we consider some topology structure on the group action, i.e. we consider G as a topological group X as a topological space, then we can define a action $G \curvearrowright X$ is **continuous** if the operation

$$\phi : G \times X \rightarrow X, \quad (g, x) \mapsto g * x$$

is a continuous map, where $G \times X$ is equipped with the product topology, then the translation $\tau_g : X \rightarrow X, x \mapsto g * x$ is a **homeomorphism** since

- τ_g can be seen as the restriction of ϕ on $\{g\} \times X$, hence it is continuous.
- the inverse of τ_g is $\tau_{g^{-1}}$, which is also continuous by above argument.

Similarly argument in the previous section, we can define the permutation representation of the continuous group action:

$$\tau : G \rightarrow \text{Homeo}(X), \quad g \mapsto \tau_g$$

where $\text{Homeo}(X)$ is the group of homeomorphisms on X with composition of functions, but that is not enough since G is a topological group when $\text{Homeo}(X)$ is **only a group**, hence some topology need to be defined here such that τ is a continuous map.

Definition. Let $C(X, Y)$ be the set of all continuous maps from topological space X to topological space Y , the **compact-open topology** on $C(X, Y)$ is generated by the subbasis

$$W(K, V) = \{f \in C(X, Y) \mid f(K) \subset V\}$$

where $K \subset X$ is compact and $V \subset Y$ is open.

with this topology, we can verify that the permutation representation of continuous group action is actually a morphism of topological groups (i.e. continuous).

Conversely, a continuous permutation representation $\tau : G \rightarrow \text{Homeo}(X)$ can not always define a continuous group action, it depends on the topology of X . By **Ellis-Arens theorem**, the converse holds if X is locally compact Hausdorff space (ref: <https://math.stackexchange.com/questions/3586125/when-are-these-two-definitions-of-a-continuous-action-noredirect=1&lq=1>).

With the basic concept in group action, we can conclude some topological properties of the action:

Proposition 3.4. Let $G \curvearrowright X$ be a continuous group action, then

(1) If X is Hausdorff, then

stabilizer G_x is a closed subgroup of G ;

the set of fixed points X_0 is closed in X .

(2) If G is compact and X is Hausdorff, then orbit $O(x)$ is homeomorphic to the quotient space G/G_x

Proof. □

An interesting part in topology is a quotient space

$$X/G = X/\sim = \{O(x) \mid x \in X\}$$

where \sim is the equivalence relation by orbits, we call it the **orbit space** of the action if we equip it with the quotient topology. An important fact is that the **quotient map** is **open** without any extra conditions:

Proof. □

Some other good properties will hold for compact group action

Proposition 3.5. *Let $G \curvearrowright X$ be a continuous group action with orbit map $p : X \rightarrow X/G$, if G is compact, both X and G are Hausdorff, then*

(1) p is a closed map.

(2) p is a **proper** map: any pre-image of compact is compact.

(3) X is compact if and only if X/G is compact.

(4) X is locally compact if and only if X/G is locally compact.

Proof. □

For an action, we always hope the orbit space can keep some good properties, so a restriction here will be helpful:

Definition. A continuous group action $G \curvearrowright X$ is **proper** if the map

$$\Phi : G \times X \rightarrow X \times X, \quad (g, x) \mapsto (x, g * x)$$

is a proper map, i.e. any compact set in $X \times X$ has a compact pre-image in $G \times X$.

Then we can conclude some good properties:

Proposition 3.6. *Let $G \curvearrowright X$ be a proper action with orbit map $p : X \rightarrow X/G$, if X is Hausdorff, then*

(1-orbit space) X/G is Hausdorff.

(2-stabilizer) For any $x \in X$, G_x is compact.

- (3-orbit) For any $x \in X$, the orbit $O(x)$ is closed in X .
- (4-quotient map) p is proper, so closed.
- (5-compactness) X is (locally) compact if and only if X/G is (locally) compact.
- (6-homeo) $G/G_x \cong O(x)$, any orbit is homemorphic to a quoitent space of topological group. (7-)

Remark 3.5. If we dont assume that X is Hausdorff, some properties will fail and something will be vague, but we do not discuss the case since we always consider X to be a Manifold or other nice objects.

Proper action is always appear together with free action to construct a covering space or principal bundle, there are a method to check two condition by following proposition:

Proposition 3.4. *Let $G \curvearrowright X$ be a continous free action, then the following conditions are equivalent:*

- (1) *The action is proper.*
- (2) *The image of the map $\Phi : G \times X \rightarrow X \times X$ is closed, and the map $\varphi : \text{im}\Phi \rightarrow G$, $(x, gx) \mapsto (g)$ is continous.*

For example, we consider gorup action $\mathbb{Z} \curvearrowright \mathbb{R}$ by translation $n * x = x + n$, the action is free clearly, then proper map

$$\Phi : \mathbb{Z} \times \mathbb{R} \rightarrow \mathbb{R} \times \mathbb{R}, \quad (n, x) \mapsto (x, n + x)$$

has the image $C = \{(x, x + n) | x \in \mathbb{R}, n \in \mathbb{Z}\}$, it is easy to prove that C is closed in $\mathbb{R} \times \mathbb{R}$, and the map $\varphi : C \rightarrow \mathbb{Z}$, $(x, x + n) \mapsto n$ is continous since we can explicitly write

$$\varphi(x, y) = y - x$$

It is a continous map to \mathbb{R} , then the restriction is surely continous, so the free action is also proper.

3.3 Lie-Group

In this section, we suppose that readers have some basic knowledge of differential manifold, for example the chart, atlas and so on, it can be found in chapter 1,2 of Lee's book «Introduction to Smooth Manifolds». The Lie group is a natural combination of topological group and differential manifold:

Definition. A Lie group is a group $(G, *, \mathcal{T})$ satisfies:

- (1) $(G, *)$ is a group.
- (2) (G, \mathcal{T}) is a smooth manifold.
- (3) The group operation is compatible with the smooth structure, i.e. the map

$$G \times G \rightarrow G, \quad (g, h) \mapsto g * h^{-1}$$

is a smooth map, where $G \times G$ is equipped with the product smooth structure.

Remark 3.6. Here are some immediate results from topological group and differential manifold, the verification is not difficult, I tend to give them as a definition here:

(1) The **morphism** of Lie group is a group homomorphism which is also a smooth map; The **isomorphism** of Lie group is a group isomorphism which is also a diffeomorphism. Which motivates us to define the category

$$\text{LieGrp} \left| \begin{array}{l} \text{objects: Lie group} \\ \text{morphisms: morphism of Lie group} \end{array} \right.$$

(2) The subgroup of a Lie Group is **not** always a Lie group: consider additive group $\mathbb{Q} \subset \mathbb{R}$ with the usual topology, here we know that \mathbb{Q} is not a manifold. A sufficient condition is that **closed** subgroup of Lie group is a Lie group (**Cartan's Theorem**).

(3) The translation of the group (by left or right) is a diffeomorphism:

$$L_g : G \rightarrow G, \quad x \mapsto g * x$$

and

$$R_g : G \rightarrow G, \quad x \mapsto x * g$$

(4) The product of two Lie group is still a Lie group under the product smooth structure and the component-wise group operation.

(5) The Lie group is always **Hausdorff** and **second countable**, since the smooth manifold structure forces it.

There are many examples of Lie group, it is a very rich area to study, here we give a proof that **The circle \mathbb{S}^1 is a Lie group**, it is an important example in topological group.

Proof. The complete proof under \mathbb{R}^2 is a bit long and boring, it is better to consider a natural real manifold structure \mathbb{C} , the unique chart is given by homeomorphism

$$\phi : \mathbb{C} \rightarrow \mathbb{R}^2, \quad z = x + iy \mapsto (x, y)$$

The unique transition map is $\phi \circ \phi^{-1} = id_{\mathbb{R}^2}$, so it is indeed a smooth manifold.

Then it is not difficult to verify a smooth map

$$\mu : \mathbb{C}^* \times \mathbb{C}^* \rightarrow \mathbb{C}^*, \quad (z, w) \mapsto \frac{z}{w}$$

hence we just need to check that $\mathbb{S}^1 = \{e^{i\theta} \mid \theta \in \mathbb{R}\}$ is a one dimensional submanifold of \mathbb{C} and then the restriction of μ on \mathbb{S}^1 is automatically smooth, which finishes the proof. \square

In genral, the check of Lie group structure is based on the structure of manifold, many topological groups with manifold structure are Lie groups, It is can be concluded by **Hilbert's fifth problem**, An formal answer is given by Yamabe in 1953, we state it without proof such that we can quickly determine some Lie group in some cases:

Theorem 3.7 (Neumann-Yamabe).

If G is a locally compact topological group, then the following statement are equivalent:

- (1) G is a Lie group.
- (2) G is locally euclidean.
- (3) G has the **no small subgroup (NSS)** properties: there is an open neighborhood U of e containing no non-trivial subgroup.

Remark 3.7. The theorem is based on the paper (ref: https://www.math.uci.edu/~isaac/Taobookreview-final.pdf?utm_source=chatgpt.com), another reference is by Terence Tao's note (ref: https://terrytao.wordpress.com/wp-content/uploads/2012/03/hilbert-book.pdf?utm_source=chatgpt.com). here are some immediate comments:

(1) \mathbb{S}^1 is a Lie group since it is compact and a one-dimensional manifold. (A Chinese saying: 杀鸡用牛刀...)

(2) A fact is that p-adic number \mathbb{Q}_p is locally compact since \mathbb{Z}_p is compact by theorem of Tychonoff, but it is not Lie group by condition NSS: we have a decreasing sequence of subgroups

$$\mathbb{Z}_p \supseteq p\mathbb{Z}_p \supseteq p^2\mathbb{Z}_p \supseteq \cdots$$

with a comparsion $p^k\mathbb{Z}_p = \{x \in \mathbb{Q}_p \mid |x|_p \leq e^{-k}\} \subset B_p(0, e^{-k+1})$ for any k .

In particular \mathbb{R} is a lie group under addition although it is very plain and trivial, but by comparing to \mathbb{Q}_p we see that \mathbb{R} has NSS property: For example take $(-1, 1)$, then any non-trivial subgroup of \mathbb{R} , if we take some non-zero element x , then there exists $n \in \mathbb{N}$ such that $|nx| > 1$ (it is the archimedean property of \mathbb{R} !).

with the help of the nice theorem, we can state some examples of Lie group without proof with some knowledge of their topology:

Example 3.7. Here are some examples of Lie group:

(1) The additive group $(\mathbb{R}^n, +)$ is a Lie group, similarly if we see \mathbb{C} as a real manifold, then $(\mathbb{C}^n, +)$ is also a $2n$ -dimension real Lie group.

(2) \mathbb{S}^1 is a Lie group, but generally \mathbb{S}^n is not necessary a Lie group, because not all \mathbb{S}^n can be well-defined as a topological group. Similar situation holds for projective space \mathbb{RP}^n , and diffeomorphism $\mathbb{RP}^1 \cong \mathbb{S}^1$ ensures projective line can be seen as a Lie group

(3) The n -dimensional torus T^n is a Lie group by the finite product of Lie group $\mathbb{S}^1 \times \dots \times \mathbb{S}^1$.

(4) The general linear group $\mathrm{GL}(n, \mathbb{R})$ is a Lie group under the matrix multiplication.

(5) Affine group $A(n, \mathbb{R})$ is a Lie group by isomorphism with $\mathrm{GL}(n, \mathbb{R}) \times \mathbb{R}^n$:

$$(x \mapsto AX + b) \longleftrightarrow (A, b)$$

4 Dual space and category

In this section, we will the structure of dual in the view of category, and then discuss some properties of dual space.

Definition 4.1. Let V be a vector space over a field K . The **dual space** of V , denoted V^* , is the set of all linear functionals from V to K :

$$V^* = \mathcal{L}(V, K) = \{f : V \rightarrow K \mid f \text{ is linear}\}.$$

Proposition 4.1. *The dual space V^* is a vector space over K with the following operations:*

- (Addition) *If $f, g \in V^*$, then $(f + g)(v) = f(v) + g(v)$ for all $v \in V$.*
- (Scalar multiplication) *If $f \in V^*$ and $\alpha \in K$, then $(\alpha f)(v) = \alpha f(v)$ for all $v \in V$.*

The dual space V^* captures the notion of linear functionals on V and provides a way to study the properties of V through its dual. Another important concept related to dual space is the dual map induced by a linear map

Proposition 4.2. *Let $T : V \rightarrow W$ be a linear map between vector spaces V and W . The **dual map** $T^* : W^* \rightarrow V^*$ is defined by*

$$T^*(g) = g \circ T$$

for all $g \in W^$, it is a linear map induced by T .*

Furthermore, T^ satisfies the following properties:*

- (Preservation of identity) *for any identity linear map $I : V^* \rightarrow V^*$, I^* is the identity linear map on V^* .*
- (Preservation of composition) *for any linear maps $T : V \rightarrow W$ and $S : W \rightarrow U$, we have $(S \circ T)^* = T^* \circ S^*$.*

Proof. To show that T^* is linear, we need to verify that it preserves addition and scalar multiplication. Let $g_1, g_2 \in W^*$ and $\alpha \in K$. Then, for any $v \in V$:

$$T^*(g_1 + g_2)(v) = (g_1 + g_2)(T(v)) = g_1(T(v)) + g_2(T(v)) = T^*(g_1)(v) + T^*(g_2)(v).$$

Thus, $T^*(g_1 + g_2) = T^*(g_1) + T^*(g_2)$.

Next, for scalar multiplication:

$$T^*(\alpha g)(v) = (\alpha g)(T(v)) = \alpha g(T(v)) = \alpha T^*(g)(v).$$

Therefore, $T^*(\alpha g) = \alpha T^*(g)$.

Since T^* preserves both addition and scalar multiplication, it is a linear map. Now, we verify the preservation of identity. Let $I : V \rightarrow V$ be the identity map. For any $g \in V^*$ and $v \in V$:

$$I^*(g)(v) = g(I(v)) = g(v).$$

Thus, $I^*(g) = g$, which shows that I^* is the identity map on V^* .

Finally, we verify the preservation of composition. Let $T : V \rightarrow W$ and $S : W \rightarrow U$ be linear maps. For any $h \in U^*$

$$(S \circ T)^*(h) = h \circ (S \circ T) = (h \circ S) \circ T = T^*(S^*(h)) = (T^* \circ S^*)(h).$$

□

After knowing the basic definition of dual space and dual map, we can conclude like following:

- We try to see dual as some function, which maps a vector space to the dual space (by proposition 4.1), so we naturally define **Vect_K** to be the set of all vector spaces over field K , then dual can be seen as a function in it

$$(-)^* : \mathbf{Vect}_K \rightarrow \mathbf{Vect}_K, \quad V \mapsto V^*$$

that means dual can be seen **as a function between classes** (In the set theory, the set of sets is called classes).

- Furthermore, dual is not only a function between classes, each linear map $T : V \rightarrow W$ induces a dual map $T^* : W^* \rightarrow V^*$ (by proposition 4.2), so we can get another information about dual: it can be seen as **a function between sets of morphisms** (in the vector spaces, a morphism is a linear map, which preserves the vector space structure), hence we can define dual as following:

$$(-)^* : \mathcal{L}(V, W) \rightarrow \mathcal{L}(W^*, V^*), \quad T \mapsto T^*$$

That is two level of dual, and we can draw a picture like following:

$$\begin{array}{ccccc} V & \xrightarrow{\quad T \quad} & W & & \\ \vdots & & \vdots & & \vdots \\ (-)^* & & (-)^* & & (-)^* \\ \vdots & & \vdots & & \vdots \\ V^* & \xleftarrow{\quad T^* \quad} & W^* & & \end{array}$$

We should pay attention to the level of dual, the first level is the function between classes, the second level is the function between sets of morphisms, we have the first level, and then we can get the second level by naturally definition, that is why category is a powerful tool! In set theory, we only have elements in a set, and then we use functions to connect two sets, but now we hope to construct a class containing sets, and then use a function to connect two classes, but that is not enough, we also need to connect a morphism of two sets in a class to another morphism of two sets in another class, that is the second level of function.

Definition 4.2 (Category). A category \mathcal{C} consists of the following data:

- a unique class of **objects**(sets or any other mathematical objects)

$$\text{Ob}(\mathcal{C});$$

- for every pair of objects $A, B \in \text{Ob}(\mathcal{C})$, a set of morphisms

$$\text{Hom}_{\mathcal{C}}(A, B);$$

- for every triple of objects $A, B, C \in \text{Ob}(\mathcal{C})$, a function called **composition**

$$\circ : \text{Hom}_{\mathcal{C}}(B, C) \times \text{Hom}_{\mathcal{C}}(A, B) \longrightarrow \text{Hom}_{\mathcal{C}}(A, C), \quad (g, f) \mapsto g \circ f;$$

- for each object $A \in \text{Ob}(\mathcal{C})$, there exists an **identity morphism**

$$\text{id}_A \in \text{Hom}_{\mathcal{C}}(A, A).$$

These data satisfy the following axioms:

Associativity: for all $f \in \text{Hom}_{\mathcal{C}}(A, B)$, $g \in \text{Hom}_{\mathcal{C}}(B, C)$, and $h \in \text{Hom}_{\mathcal{C}}(C, D)$:

$$h \circ (g \circ f) = (h \circ g) \circ f.$$

Identity: for all $f \in \text{Hom}_{\mathcal{C}}(A, B)$,

$$f \circ \text{id}_A = f = \text{id}_B \circ f.$$

Remark 4.1. we often write the following to simplify the notation:

$$A \in \mathcal{C} \iff A \in \text{Ob}(\mathcal{C})$$

and

$$f : A \rightarrow B \iff f \in \text{Hom}_{\mathcal{C}}(A, B)$$

In set theory, we often see element as a point, similarly, in category theory, we often see object as a point, and morphism as an arrow between two points, so the category can be draw as a graph like following:

In the category we defined above, we only have four objects so by definition we at least have four identity morphisms (arrows start and end at the same point); and we only define two morphisms between different objects, i.e. $f : A \rightarrow B$ and $g : B \rightarrow C$, by composition we can get another morphism $g \circ f : A \rightarrow C$, so actually we have six morphism in this category.

Category is a strong concept to generalized the objects in mathematics.

Example 4.1.

(1) The category of sets:

Set	object: all sets
	morphisms: functions between sets

Here a famous paradox in set theory is **Russell's paradox**, that shows that there does not exists a set containing all sets, otherwise a contradiction will arise according to the axiom of set theory. To avoid the paradox, we use classes instead of sets to define category, but that is not enough, because sometimes we hope to talk about the category of all categories, so a strong axiom called **Grothendieck universes** is needed here.

(2) The caetgory of groups:

Grp	object: all groups
	morphisms: group homomorphisms

(3) The category of topological spaces:

Top	object: all topological spaces
	morphisms: continuous maps

(4) The category of vector spaces over a field K :

$$\mathbf{Vect}_K \left| \begin{array}{l} \text{object: all vector spaces over } K \\ \text{morphisms: linear maps} \end{array} \right.$$

In category, we usually ignore the elements of an object, and only care about the morphisms between two objects, so we will care about whether the morphism is injective, surjective or bijective. However, in the traditional definition of functions, the statement will depend on the elements of the set, so a lemma will be need here to generalized the definition of injection and so on in category.

Lemma 4.3. *Let $f : A \rightarrow B$ be a function between two sets, then*

(1) *f is injective if and only if for any set X and any two functions $g_1, g_2 : X \rightarrow A$, the left-cancellation holds:*

$$f \circ g_1 = f \circ g_2 \Rightarrow g_1 = g_2$$

(2) *f is surjective if and only if for any set X and any two functions $h_1, h_2 : B \rightarrow X$, the right-cancellation holds:*

$$h_1 \circ f = h_2 \circ f \Rightarrow h_1 = h_2$$

That will be very useful in the proof referring to universal properties. Another special morphism in a category is isomorphism, the definition is naturally same in group, vector space and so on.

Definition 4.3. Let \mathcal{C} be a category and $A, B \in \text{Ob}(\mathcal{C})$, a morphism $f : A \rightarrow B$ is called an **isomorphism** if there exists a morphism $g : B \rightarrow A$ such that

$$g \circ f = \text{id}_A, \quad f \circ g = \text{id}_B$$

In this case, we say that A and B are isomorphic, denoted by $A \cong B$.

Now with the basic knowledge of category, we can study the functor, the "function" between two categories, as like what we talked just now, dual can be seen as a functor between two categories.

Definition 4.4. Let \mathcal{C} and \mathcal{D} be two categories, a functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is a map in two levels:

- a function

$$F : \text{Ob}(\mathcal{C}) \rightarrow \text{Ob}(\mathcal{D}), \quad A \rightarrow F(A)$$

- For each A, B , a function

$$F : \text{Hom}_{\mathcal{C}}(A, B) \rightarrow \text{Hom}_{\mathcal{D}}(F(A), F(B)), \quad f \rightarrow F(f)$$

the map should satisfy the following axioms:

- $F(\text{id}_A) = \text{id}_{F(A)}$ for all $A \in \text{Ob}(\mathcal{C})$.
- $F(g \circ f) = F(g) \circ F(f)$ for all $f : A \rightarrow B$ and $g : B \rightarrow C$ in \mathcal{C} .

The reason of axioms is similar to linear map or group homomorphism: To preserve the structure! In another view, without the axioms, the image of functor may not be a category. (Taking mind that a map non-trivially preserving structure will reflect the relation between two objects, that appears everywhere in mathematics).

Reback to dual space, by the discussion above, we want to conclude that dual is a functor, so we naturally take a category \mathbf{Vect}_K containing all vector spaces over field K , and proposition 4.1 shows that dual can be seen as a function between objects of \mathbf{Vect}_K , so $(-)^*$ defines a functor from \mathbf{Vect}_K to \mathbf{Vect}_K at the first level? Unluckily, that is not true, by proposition 4.2, we find that dual maps a linear map $T : V \rightarrow W$ to a linear map $T^* : W^* \rightarrow V^*$ instead of $T^* : V^* \rightarrow W^*$, but that is not a big problem, we are now close to the natural of dual. that means reversing anything, even the category!

Definition 4.5. For any category \mathcal{C} , the **opposite category** \mathcal{C}^{op} is defined as following:

$$\mathcal{C}^{op} \mid \begin{array}{l} \text{object: } \text{Ob}(\mathcal{C}^{op}) = \text{Ob}(\mathcal{C}) \\ \text{morphisms: } \text{Hom}_{\mathcal{C}^{op}}(A, B) = \text{Hom}_{\mathcal{C}}(B, A) \end{array}$$

The definition needs some explanation, in the level of morphisms, we see a morphism $f : A \rightarrow B$ as a morphism $f^{op} : B \rightarrow A$ by reversing the direction as following:

$$A \xrightarrow{\quad f \quad} B \\ \xleftarrow{\quad f^{op} \quad}$$

so the example we gave after the definition of category can be draw as following:

What we do is just to reversing the direction of arrows! Hence finally we can conclude that dual is a **functor** from \mathbf{Vect}_K to \mathbf{Vect}_K^{op} :

$$\begin{aligned}
 & \text{object: } V \in \text{Ob}(\mathbf{Vect}_K) \mapsto V^* \in \text{Ob}(\mathbf{Vect}_K^{op}) = \text{Ob}(\mathbf{Vect}_K) \\
 (-)^* \Big| & \\
 & \text{morphisms: } T \in \text{Hom}_{\mathbf{Vect}_K}(V, W) \mapsto T^* \in \text{Hom}_{\mathbf{Vect}_K^{op}}(V^*, W^*) = \text{Hom}_{\mathbf{Vect}_K}(W^*, V^*)
 \end{aligned}$$

Finite dimensional: transpose

This section can be seen as an example of dual space in linear algebra, where the dual map is closely related to the concept of the transpose of a matrix. In this section, V and W always denote finite-dimensional vector spaces over a field K .

Firstly, we study the basic structure of dual space

$$V^* = \text{Hom}_K(V, K)$$

A natural question is: What is the dimensional of (V^*) ? What is the basis of V^* ? The answer is directly from a decomposition of a linear functional, it is completely determined by the properties of linear map: We take a linear functional $f : V \rightarrow K$ and express it in terms of a basis $\{e_i\}$ of V ,

$$f(x) = f\left(\sum_i x_i \cdot e_i\right) = \sum_i f(e_i)x_i$$

for some scalars $x_i \in K$, then we hope to find a linear functional mapping x to x_i , it is natural to define a projection

$$\phi_i(x) = \phi_i\left(\sum_k x_k \cdot e_k\right) = x_i$$

It is easy to verify that ϕ_i is a linear functional, and then any linear functional f can be expressed as

$$f = \sum_i f(e_i)\phi_i$$

And we can prove that the list $\{\phi_i\}$ is a basis of V^* : suppose $\dim V = n$, and see the scalar equation

$$c_1\phi_1 + \cdots + c_n\phi_n = 0$$

just take some element of basis e_j into the equation, then we get $c_j = 0$ for all j , hence $\{\phi_i\}$ is linearly independent, and then it is a basis of V^* . Therefore we conclude that

Claim 4.4. *Let $\mathcal{B} = \{e_1, e_2, \dots, e_n\}$ be a basis of V , then the **dual basis** $\mathcal{B}^* = \{\phi_1, \phi_2, \dots, \phi_n\}$ defined by*

$$\phi_j(v_i) = \delta_{ij} = \begin{cases} 1 & i = j \\ 0 & i \neq j \end{cases}$$

It is a basis of V^ , i.e. $\dim V^* = \dim V$.*

The result does not hold when the dimension is infinite, a classical result is the dual space of polynomial space (more generally a free A -module with infinite basis), we take $V = \mathbb{R}[X]$, and $f : \mathbb{R}[X] \rightarrow \mathbb{R}$ be a linear functional, notice that linear map will be determined by the image of basis uniquely, so we just need to define $f(X^n) = c_n$, so any sequence $(c_n)_{n \in \mathbb{N}}$ will be corresponding to a linear functional uniquely, hence we have isomorphism

$$(\mathbb{R}[X])^* \cong \mathbb{R}^{\mathbb{N}} = \prod_{n=0}^{\infty} \mathbb{R}$$

more generally in module theory, we have a generalized result

$$\text{Hom}_A(A^{(I)}, M) = M^I$$

for any A -module M and any set I . The example is a little ALGEBRA, following example will be more analysis, that shows dual space of a function space will contain the linear functional which gives the method to evaluate function.

Example 4.2. We consider $V = C[0, 1]$, it is actually a Banach space with the sup norm. Now we consider a linear functional $F \in V^*$ such that $F(f) = f(0)$, the functional evaluates the function at point 0.

If $(f_n)_{n \in \mathbb{N}}$ is a sequence of functions in $C[0, 1]$, then $F(f_n) = f_n(0)$ will evaluate the sequence at point 0. Especially, if the sequence converges under the sup norm, that means the sequence converges uniformly to some function f , then naturally we have convergence at point 0:

$$f_n(0) \rightarrow f(0), \quad n \rightarrow \infty$$

In the view of functional, F is continuous so we have

$$\lim f_n(0) = \lim F(f_n) = F(\lim f_n) = F(f) = f(0)$$

this is a higher view that convergence uniform implies pointwise convergence, let see another linear functional

$$I : C[0, 1] \rightarrow \mathbb{R}, \quad f \mapsto \int_0^1 |f(x)| dx$$

It is also a continuous linear functional, we take a sequence $f_n = x^n(1 - x)$, then

$$I(f_n) = \int_0^1 x^n(1 - x) dx = \frac{1}{(n+2)(n+1)} \rightarrow 0$$

which shows that even if the sequence does not converges uniformly, but if we change a view of convergence, for example convergence in integral sense, then we will get a type of convergence.

In conclusion, the dual space of function space is badly larger than the function space, in it continuous linear functional will be a kind of functional useful in sense of analysis.

With the basic knowledge of dual space, we turn our eyes to the dual map, i.e. linear map between dual spaces, a linear map $T : V \rightarrow W$ induces a dual map $T^* : W^* \rightarrow V^*$ as following diagram

$$\begin{array}{ccc} V & \xrightarrow{T} & W \\ & \searrow & \downarrow f \\ & T^*(f) & K \end{array}$$

As we know dual map can be seen as result of functor on the set of morphisms, in particular the set of linear maps between two vector spaces is still a vector space, so the functor induces a linear map as following:

$$(-)^* : \mathcal{L}(V, W) \rightarrow \mathcal{L}(W^*, V^*), \quad T \mapsto T^*$$

where $T^*(f) = f \circ T$ for any $f \in W^*$ is the **dual map** induced by T . So naturally we have following properties of dual map:

Claim 4.5. Suppose $T, S \in \mathcal{L}(V, W)$ and $\lambda \in K$, then

$$(1) (T + S)^* = T^* + S^*$$

$$(2) (\lambda T)^* = \lambda T^*$$

$$(3) (\text{id}_V)^* = \text{id}_{V^*}$$

$$(4) (S \circ T)^* = T^* \circ S^*$$

It is interesting to study the linear map $(-)^*$, which will give some relations between a linear map and its dual map.

$$\ker(-)^* = \{T \in \mathcal{L}(V, W) \mid f \circ T = 0 \text{ for all } f \in W^*\}$$

We can prove that the kernel is trivial by contradiction: suppose there exists some non-zero linear map $T \in \ker(-)^*$, then there exists some $v \in V$ such that $w = T(v) \neq 0$, so

$$f(w) = 0 \quad \forall f \in W^*$$

However, if we take a basis containing w , then a corresponding dual basis contains a linear functional $\phi_w : W \rightarrow K$ such that $\phi_w(w) = 1$, hence we get a contradiction. Hence $(-)^*$ is an injective linear map, together with the claim 4.4, we know that

$$\dim \mathcal{L}(V, W) = \dim \mathcal{L}(W^*, V^*)$$

Which implies that $(-)^*$ is an **isomorphism**! Linear map between two dimensional vector space can be denoted by a matrix under some basis, if $\dim V = n$ and $\dim W = m$, then a linear map $T \in \mathcal{L}(V, W)$ can be represented by an $m \times n$ matrix, and then the dual map $T^* \in \mathcal{L}(W^*, V^*)$ can be represented a $n \times m$ matrix, so a natural hypothesis is that dual $(-)^*$ can be seen as the **transpose** of a matrix:

Take $\mathcal{B} = e_1, \dots, e_n$ be a basis of V and $\mathcal{C} = \{w_1, \dots, w_m\}$ be a basis of W , then the dual basis are $\mathcal{B}^* = \{\phi_1, \dots, \phi_n\}$ and $\mathcal{C}^* = \{\psi_1, \dots, \psi_m\}$. Suppose the matrix of T under basis \mathcal{B} and \mathcal{C} is $A = (a_{ij})_{m \times n}$, and the matrix of T^* under basis \mathcal{C}^* and \mathcal{B}^* is $B = (b_{ij})_{n \times m}$ that means

$$T(e_j) = \sum_{i=1}^m a_{ij} w_i, \quad T^*(\psi_i) = \sum_{j=1}^n b_{ij} \phi_j$$

Then we can compute the dual map T^* under basis \mathcal{C}^* and \mathcal{B}^* :

$$T^*(\psi_k)(e_l) = \psi_k(T(e_l)) = \psi_k\left(\sum_{r=1}^m a_{rl} w_r\right) = \sum_{r=1}^m a_{rl} \psi_k(w_r) = a_{kl}.$$

On the other hand,

$$T^*(\psi_k)(e_l) = \left(\sum_{p=1}^n b_{pk} \phi_p\right)(e_l) = \sum_{p=1}^n b_{pk} \phi_p(e_l) = b_{lk}.$$

Comparing the two expressions gives

$$a_{kl} = b_{lk},$$

so the matrix of T^* under two dual bases is the transpose of A under two bases.

We can finish the result by the view of category: in this section we talk about finite-dimensional vector spaces over K , i.e. category

$$\mathbf{Vect}_K^f \mid \begin{array}{l} \text{objects: finite-dimensional vector spaces over } K \\ \text{morphisms: linear maps} \end{array}$$

If $\dim V = n$, then $V \cong K^n$, so we can define the category of matrices over K :

$$\mathbf{Mat}_K \mid \begin{array}{l} \text{objects: } K^n \\ \text{morphisms: matrices over } K \end{array}$$

The category can be seen as a subcategory of \mathbf{Vect}_K^f by an embedding functor

$$\mathbf{J} : \mathbf{Mat}_K \hookrightarrow \mathbf{Vect}_K^f \mid \begin{array}{l} \text{objects: } K^n \mapsto K^n \\ \text{morphisms: } A \mapsto (v \mapsto Av) \end{array}$$

We can prove that \mathbf{J} is an equivalence of categories (faithful, full and essentially surjective), hence we can identify \mathbf{Mat}_K and \mathbf{Vect}_K^f in the view of category. We have already know a dual functor $(-)^*$ inside \mathbf{Vect}_K^f , and in above we have already proved that a dual map can be seen as the transpose of a matrix, then we can define transpose functor as following:

$$\mathbf{T} : \mathbf{Mat}_K \rightarrow \mathbf{Mat}_K^{\text{op}} \mid \begin{array}{l} \text{objects: } K^n \mapsto K^n \\ \text{morphisms: } A \mapsto A^t \end{array}$$

Then by the identification of two categories, we know that dual functor $(-)^*$ and transpose functor \mathbf{T} are "the same" as dual functor by verification (Joke: reader is the coauthor of category theory paper qwq), so we can conclude the result as following

Claim 4.6. *Dual map can be seen as the transpose of a matrix under some basis*

$$[T^*]_{C^* \rightarrow B^*} = [T]_{B \rightarrow C}^t$$

more precisely, the following diagram commutes up to natural isomorphism:

$$\begin{array}{ccc} \mathbf{Mat}_K & \xrightarrow{\mathbf{T}} & \mathbf{Mat}_K^{\text{op}} \\ \mathbf{J} \downarrow & & \downarrow \mathbf{J} \\ \mathbf{Vect}_K^f & \xrightarrow{(-)^*} & \mathbf{Vect}_K^{f, \text{op}} \end{array}$$

Hence we have same algebraic properties of transpose:

- $(A + B)^t = A^t + B^t$
- $(\lambda A)^t = \lambda A^t$

- $(I_n)^t = I_n$
- $(AB)^t = B^t A^t$

5 Differential form

The first section will start from simple example in calculus to show the basic idea of differential form. The definition of differential form can be start from FTC (Fundamental Theorem of Calculus): For a differentiable function $f : [a, b] \rightarrow \mathbb{R}$, we have

$$\int_a^b f'(x) dx = f(b) - f(a)$$

Or more generally, for a smooth curve $\gamma : [a, b] \rightarrow \mathbb{R}^n$ and a smooth function $f : \mathbb{R}^n \rightarrow \mathbb{R}$, we have

$$\int_{\gamma} \nabla f \cdot d\mathbf{r} = f(\gamma(b)) - f(\gamma(a))$$

where $\nabla f = \left(\frac{\partial f}{\partial x_1}, \dots, \frac{\partial f}{\partial x_n} \right)$ is the gradient of f , and $d\mathbf{r} = (dx_1, \dots, dx_n)$ is the differential of position vector. In first example, we can see $f'(x)dx$ as a form of df , it is the differential of function f , then we can rewrite the FTC as

$$\int_{[a,b]} df = \int_{\partial[a,b]} f$$

The idea here is really simple, we just see the left integral as a accumulation of infinitesimal changes of f along the interval $[a, b]$

$$\sum_{t \in P_n} \Delta f(t) \approx \int_{[a,b]} df$$

where P_n is a partition of $[a, b]$ by choosing n points, and if the partition is fine enough, then the sum will be close to the **REAL** integral, it is the basic idea of Riemann integral.
