Theorem 1.1 (Dirichlet's unit theorem).

Let K be a number field with r real embeddings and s pairs complex embeddings, and let  $\mathcal{O}_K$  be its integer ring, then its unit group has isomorphic structure:

$$\mathcal{O}_K^{\times} \cong \mu(K) \times \mathbb{Z}^{r+s-1}$$

where  $\mu(K)$  is the group of roots of unity in K, and it is a finite cyclic gourp.

Take  $K = \mathbb{Q}(\sqrt[3]{2})$  be the extension field of the raitional number, and we denote  $\theta = \sqrt[3]{2}$ , then each element in its has the form

$$a + b\theta + c\theta^2$$
 with  $a, b, c \in \mathbb{Q}$ 

Then we prove some properties of the field:

**Proposition 1.2.** in  $\mathbb{Q}(\sqrt[3]{2})$  we have

- r = 1 and s = 1.
- $N_{\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}}(a+b\theta+c\theta^2)=a^3+2b^3+4c^3-6abc$
- $u = 1 + \theta + \theta^2$  is a unit and its inverse is  $v = -1 + \theta$ .
- The group of the unity is  $\mu = \{\pm 1\}$

*Proof.* Firstly we suppose that  $\sigma: \mathbb{Q}(\sqrt[3]{2}) \hookrightarrow \mathbb{C}$  is a field embedding, then surely  $\sigma(1) = 1$ . Let  $f(X) = X^3 - 2$  be a polynoimal, and notice that  $f(\theta) = 0$ , then

$$0 = \sigma(f(\theta)) = f(\sigma(\theta))$$

Clearly  $\sigma(\theta)$  must be the root of f in  $\mathbb{C}$ , so we can conclude the roots are  $\theta, \theta w, \theta w^2$ , where  $w = e^{2i\pi/3}$ . Hence the unique real embedding is  $\sigma = id$  and there are two conjugate complex embedding.

For the norm we consider the Q-linear map  $l_x$  with  $x = a + b\theta + c\theta^2$ , then

$$l_x(1) = a + b\theta + c\theta^2, l_x(\theta) = 2c + a\theta + b\theta^2, l_x(\theta^2) = 2b + 2c\theta + a\theta^2$$

so we can conclude the norm by

$$det[l_x]_{\{1,\theta,\theta^2\}} = \begin{vmatrix} a & 2c & 2b \\ b & a & 2c \\ c & b & a \end{vmatrix} = a^3 + 2b^3 + 4c^3 - 6abc$$

and we take  $u = 1 + \theta + \theta^2$ , then N(u) = 1 + 2 + 4 - 6 = 1, so it is a unit.

For the group of the unity, we notice that  $\mathbb{Q}(\sqrt[3]{2}) \subset \mathbb{R}$  as a subfield, and  $x^n = 1$  only has possible solutions  $\{\pm 1\}$  in  $\mathbb{R}$  for any  $n \in \mathbb{N}$ , so we can conclude our result.

Return to the original equation, now we can give a equivalent statement:

**Proposition 1.3.** The integral solution of the equation  $x^3 - 2y^3 = 1$  is

$$\{(x,y) \in \mathbb{Z} | x - y\theta = u^k, \text{ for some } k \in \mathbb{Z}\}$$

*Proof.* We notice that  $x^3 - 2y^3 = 1$  can be rewritten as  $N_{\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}}(x - y\theta) = 1$ . And by the Dirichlet's unit theorem, its unit group is of the form  $\{\pm 1\} \times < u >$ . Notice that  $N_{\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}}(-1) = -1$ , so

$$N_{\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}}(-u^n) = N_{\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}}(-1)N_{\mathbb{Q}(\sqrt[3]{2})/\mathbb{Q}}^n(u) = -1, \quad \forall n \in \mathbb{Z}$$

Hence the integral solution is of the form  $u^k$  in  $\mathbb{Q}(\sqrt[3]{2})$ .

Notice that if k=0 we can get the trival solution (1,0); if k=-1, we can find that  $u^{-1}=-1+\theta$  and then get another solution (-1,-1); So we need to prove that for any other k,  $x-y\theta=u^k$  has no solution, one possible method is to prove that for any other  $u^k$ , the cofficient with respect to base vector  $\theta^2$  is non-zero. For the case k>0, by multinomial formula we can formulate

$$(1 + \theta + \theta^2)^k = \sum_{i+j+k=n} \frac{n!}{i!j!k!} \theta^{j+2k}$$

with  $\theta^3 = 2$  we can rewrite it to get a linear combination of  $\{1, \theta, \theta^2\}$ , clearly here the cofficient of  $\theta^2$  will not be zero so the choice of k will be limited to be less than zero. However, when  $k \leq -2$  we will find that it is difficult to analyse, for example

$$u^{-2} = v^{2} = 1 - 2\theta + \theta^{2}$$

$$u^{-3} = v^{3} = 1 + 3\theta - 3\theta^{2}$$

$$u^{-4} = v^{4} = -7 - 2\theta + 6\theta^{2}$$

The problem here is difficult to formulate  $u^{-k}$  since there exists negative cofficient in  $v = -1 + \theta$ , it is not easy to deduce that whether the cofficient of  $\theta^k$  will vanish in a certain k or not, the argument here will be not clear. Hence we need to use p-adic method.

#### 2 p-adic

We need to use p-adic analytic function , in particular logarithm and exponential function.

**Lemma 2.1.** Let  $x \mapsto (1+n)^x$  be the function from  $\mathbb{Z}_p$  to  $\mathbb{Q}_p$ , then there is a interpolation

$$(1+n)^x = e^{x\log(1+n)}$$

if  $|n|_p < p^{-1/p-1}$  and  $p \neq 2$ .

Proof.
